**OBJET :** demande de Brevet, n° 1102600, déposée le 25 Août 2011  
**Rapport de recherche préliminaire sans obligation de réponse**

Madame, Monsieur,

J'ai l'honneur de vous adresser en annexe **le rapport de recherche préliminaire** pour la demande de brevet citée en référence. Ce rapport cite les documents qui peuvent être pris en considération pour apprécier la nouveauté et l'activité inventive de l'invention, objet de votre demande de brevet. Il est accompagné, le cas échéant, d'une opinion écrite.

Conformément aux dispositions des articles R. 612-57 à R. 612-60 du code de la propriété intellectuelle, vous disposez d'un délai de **3 mois** à compter de la date de réception de ce rapport de recherche préliminaire pour formuler une réponse par écrit. Ce délai peut être **renouvelé une fois** sur simple requête de votre part, avant son expiration.

Votre réponse peut consister :

- **en des observations** à l'appui des revendications maintenues, aux fins de discuter de l'opposabilité des documents cités ;
- **en une nouvelle rédaction des revendications**, éventuellement accompagnée d'observations. En cas de dépôt de nouvelles revendications, les changements apportés aux revendications doivent être signalés.

Veuillez agréer, Madame, Monsieur, l'expression de ma considération distinguée.

**voir feuille séparée**

**Ad point V**

**Déclaration motivée quant à la nouveauté, l'activité inventive et la possibilité d'application industrielle ; citations et explications à l'appui de cette déclaration**

- 1 Il est fait référence au document suivant:  
D1: US 4,503,502
- 2 La présente invention concerne un système pour automatiser la surveillance active de la température d'une enceinte de cuisson.
- 3 L'état de la technique le plus proche est connu du document D1 qui montre un tel système comprenant aussi une application logicielle installée sur le mémoire d'un ordinateur, une sonde dédiée à la mesure de température et un terminal d'acquisition de cette température.
- 4 Le problème associé à cet état de la technique est qu'il ne fonctionne pas avec une table de cuisson électrique. Par ailleurs la connexion entre la sonde dédiée à la mesure de la température et l'ordinateur n'est pas standardisée.
- 5 L'invention résout ces problèmes par un terminal de puissance qui applique ou interrompt le secteur monophasé 220 Volts de la table de cuisson. De plus, il est prévu un bus USB 2.0 sur lequel le terminal d'acquisition de la température et le terminal de puissance sont connectés.

**Ad point VII**

**Certaines irrégularités relevées dans la demande**

- 6 La description ne mentionne pas l'état de la technique pertinent qui est divulgué dans D1 et ne cite pas ce document.
- 7 La revendication 1 n'est pas présentée en deux parties, alors qu'une telle présentation serait appropriée en l'espèce. Il conviendrait ainsi d'inclure dans le préambule les caractéristiques qui, combinées entre elles, font partie de l'état de la technique, et d'introduire dans la partie caractérisante les caractéristiques restantes.

**Ad point VIII**

**Certaines observations relatives à la demande**

- 8 L'objet des revendications 1, 2, 4 et 5 n'est pas clair.
- 8.1 La revendication 1 fait référence à "l'ordinateur" et "la table de cuisson" en utilisant l'article défini bien que ces composants ne soient pas mentionnés auparavant. La revendication 4, en faisant référence à "le couple des deux modules", comporte le même problème.
- 8.2 Le terme "diagramme", employé dans la revendication 2, est vague et imprécis, et laisse subsister un doute quant à la signification de la caractéristique technique à laquelle il se rapporte, au point que l'objet de ladite revendication n'est pas clairement défini.
- 8.3 Le terme "module ME 630", employé dans la revendication 5, ne définit pas les caractéristiques techniques de ce module.

(54) **Datenschnittstellengesteuerte Mehrfachsteckdose**

(57) Die Erfindung betrifft eine Anordnung zur Stromversorgung von Peripheriegeräten eines elektronischen Geräts (1) mit wenigstens einer Datenübertragungsschnittstelle. Die Aufgabe wird erfindungsgemäß dadurch gelöst, indem eine Anordnung zur Stromversorgung von Peripheriegeräten (2, 3, 4) eines elektronischen

Geräts (1) mit wenigstens einer Datenübertragungsschnittstelle vorgesehen ist, wobei die Anordnung wenigstens eine Steckdose (14) und einen Netzanschlussstecker (12) aufweist sowie eine Datenübertragungsschnittstelle (10), welche zur Steuerung des Einschaltens und Ausschaltens der Steckdose (14) vorgesehen ist.

**FIG. 1**

EP 1 231 681 A1

## Beschreibung

**[0001]** Die Erfindung betrifft eine Anordnung zur Stromversorgung von Peripheriegeräten eines elektronischen Geräts mit wenigstens einer Datenübertragungsschnittstelle.

**[0002]** In den vergangenen Jahren hat sich der USB (Universal Serial Bus)-Anschluss als Datenübertragungsschnittstelle bei Computern als Standardschnittstelle durchgesetzt. Dieser Bus hat neben der Funktion der Datenübertragung auch die Aufgabe die Stromversorgung für kleinere angeschlossene Peripheriegeräte wie zB. Scanner zu übernehmen. Der Leistungsbereich der Stromversorgung ist jedoch sehr begrenzt.

**[0003]** Aus JP 2000-231969 ist eine Vorrichtung bekannt, welche einen sogenannten USB-Hub enthält, welcher mehrere USB-Anschlüsse miteinander verbindet, sowie ein Netzteil, welches eine Netzspannung in eine Gleichspannung zur Versorgung angeschlossener USB-Peripheriegeräte zur Verfügung stellt. Des weiteren ist eine Steckdose vorgesehen, an die ein weiteres elektrisches Gerät angeschlossen werden kann.

**[0004]** Es ist Aufgabe der vorliegenden Erfindung, insbesondere die Stromversorgung von Peripheriegeräten eines Computers durch eine zentrale Stromversorgung sicherzustellen, welche vom Computer gesteuert werden kann. Des weiteren soll so der Stromverbrauch der Peripheriegeräte im sogenannten Stand-by Modus auf Null reduziert werden.

**[0005]** Die Aufgabe wird erfindungsgemäß dadurch gelöst, indem eine Anordnung zur Stromversorgung von Peripheriegeräten eines elektronischen Geräts mit wenigstens einer Datenübertragungsschnittstelle vorgesehen ist, wobei die Anordnung wenigstens eine Steckdose und einen Netzanschlusstecker aufweist sowie eine Datenübertragungsschnittstelle, welche zur Steuerung des Einschaltens und Ausschaltens der Steckdose vorgesehen ist.

**[0006]** Eine solche Anordnung bietet den großen Vorteil, dass die Stromzufuhr zu den Peripheriegeräten eines elektronischen Geräts von diesem selbst gesteuert werden kann. Das elektronische Gerät wird meistens ein PC oder Laptop bzw. Notebook sein, da diese Geräte über Datenübertragungsschnittstellen verfügen, es können aber auch andere elektronische Geräte mit einer solchen Schnittstelle sein. Dazu zählen zB. Set-Top Boxen für das digitale Fernsehen oder digitale Videorekorder. Sobald z.B. ein Computer eingeschaltet wird, liegt an der Datenübertragungsschnittstelle des Computers eine Spannung an. Diese liegt über ein Kabel verbunden auch an der Datenschnittstelle der Anordnung zur Stromversorgung an und betätigt einen Schalter. Damit werden die in der Anordnung vorhandenen Steckdosen eingeschaltet und die Peripheriegeräte mit Strom versorgt. Auf diese Art und Weise können beliebige Peripheriegeräte verwendet werden, auch solche, die nicht über eine entsprechende Datenschnittstelle verfügen, da keine Kommunikation zwischen den Peri-

pheriegeräten und dem Computer erforderlich ist. Da die Anordnung zur Stromversorgung unmittelbar am Stromnetz hängt, können auch leistungsstarke Peripheriegeräte problemlos mit Strom versorgt werden. Dies ist wichtig, da die heute oft verwendete Datenschnittstelle nach dem USB-Standard nur Peripheriegeräte mit kleiner elektrischer Leistungsaufnahme mit Strom versorgen kann. Zusätzlich werden die Peripheriegeräte vollständig vom Stromnetz getrennt, wenn der Computer ausgeschaltet wird, da damit am Schalter der Anordnung zur Stromversorgung keine Spannung mehr anliegt und diese somit ausgeschaltet wird. Die Netzschalter der einzelnen Peripheriegeräte müssen somit nicht mehr betätigt werden. Dies erhöht den Komfort und reduziert den Stromverbrauch bei abgeschaltetem Computer auf Null. Dies ist um so bedeutender, als viel Peripheriegeräte aus Kostengründen überhaupt nicht mehr über einen Netzschalter verfügen und somit ständig im Stand-by Modus Strom ziehen würden. dies wird mit der erfindungsgemäßen Anordnung zuverlässig verhindert.

**[0007]** Die Ausgestaltung nach Anspruch 2 zeichnet sich dadurch aus, dass als Datenschnittstelle der USB-Anschluss genutzt wird. Jeder aktuelle Computer ob Tischgerät oder tragbares Gerät verfügt heute über einen solchen USB-Anschluss. Damit ist sichergestellt, dass die erfindungsgemäße Anordnung mit allen auf dem Markt befindlichen Computern zusammenarbeiten kann.

**[0008]** Mit der Ausgestaltung nach Anspruch 3 ist eine individuelle Ansteuerung einzelner Steckdosen möglich. So wird nun nicht mehr nur unterschieden, ob an der Datenschnittstelle eine Spannung anliegt: oder nicht, sondern der Computer kann einzelne Steckdosen ein- und ausschalten. Damit sind dann nur die Peripheriegeräte mit Strom versorgt, auf die der Computer gerade zugreift. Wenn zB. ein Ausdruck gemacht werden soll, wird der Drucker mit Strom versorgt. Wird hingegen eine Zeichnung eingescannt, wird nur der Scanner mit Strom versorgt. So wird der Stromverbrauch auch beim Betrieb des Computers durch selektive Schaltung der Peripheriegeräte reduziert

**[0009]** Die Ausgestaltung nach Anspruch 4 stellt eine besonders einfache Möglichkeit dar, die Steckdosen zu schalten. Liegt an der Datenübertragungsschnittstelle eine Spannung an, wird ein Relais aktiviert, welches die Steckdosen an die Netzspannung schaltet. Sobald die Datenübertragungsschnittstelle keine Spannung mehr führt, schaltet das Relais die Steckdosen wieder ab. Somit werden die Steckdosen eingeschaltet, sobald der Computer eingeschaltet ist, und sie werden wieder ausgeschaltet, wenn der Computer ausgeschaltet ist. Da Relais kostengünstig sind, ist so eine preiswerte Realisierung der erfindungsgemäßen Anordnung möglich.

**[0010]** Wird als Datenübertragungsschnittstelle ein USB-Anschluss verwendet, so bietet die Ausgestaltung nach Anspruch 5 den Vorteil, dass neben der Steuerung der Stromversorgung an den gleichen USB-Anschluss

ein weiteres USB-Peripheriegerät angeschlossen werden kann Halbleiterschalter wie zB. Opto-Relais oder Halbleiterrelais benötigen nur einen geringen Steuerstrom. Somit kann an den selben USB-Anschluss eine weitere Last angeschlossen werden.

**[0011]** Mit der Ausgestaltung nach Anspruch 6 wird ein separates Einschalten aller an den Computer angeschlossenen Peripheriegeräte überflüssig. Dies erhöht den Bedienkomfort, da die Peripheriegeräte mit dem Einschalten des Computers betriebsbereit sind.

**[0012]** Die Ausgestaltungen nach Anspruch 7 und 8 haben den Vorteil, dass neben der Steuerung der Stromversorgung gleichzeitig noch die Verkabelung der Datenströme mittels ein und der selben Anordnung möglich ist. Mit mehreren USB-Anschlüssen können mehrere Peripheriegeräte mit dem Computer kommunizieren. Dies ist sinnvoll, da die meisten Computer nur über zwei USB-Anschlüsse verfügen und daher für mehrere Peripheriegeräte ein USB-Verteiler, ein sogenannter USB-Hub sinnvoll ist. Solche USB-Hubs werden normaler Weise als Einheit gefertigt. Es ist daher fertigungstechnisch einfach zu bewerkstelligen, einen solchen fertigen USB-Hub an die USB-Datenschnittstelle der erfindungsgemäßen Anordnung zur Stromversorgung anzuschließen und in das Gehäuse mit zu integrieren. Somit bilden USB-Hub und Mehrfachsteckdose eine Einheit, welche weniger Platz benötigt und sämtliche angeschlossenen Peripheriegeräte nicht nur mit Strom versorgt, sondern auch an den USB-Anschluss des Computers anbindet.

**[0013]** Die Stromversorgung leistungsstarker Geräte wie Drucker ist somit sichergestellt, da diese sonst über den USB-Anschluss selbst nicht mit ausreichend Strom versorgt werden könnten.

**[0014]** Auch die Ausgestaltung nach Anspruch 9 bietet vor allem fertigungstechnische Vorteile. Die Verwendung konventioneller Mehrfachsteckdosenleisten reduziert die Kosten. Des weiteren ist in diesen Mehrfachsteckdosenleisten fast immer noch ungenutzter Raum vorhanden, in den die Datenübertragungsschnittstelle mit den notwendigen Schaltmitteln eingebaut werden kann. Auch ein USB-Hub ist in vielen Mehrfachsteckdosenleisten noch unterzubringen, ohne dass sich das Gesamtvolumen erhöht.

**[0015]** Ausführungsbeispiele der vorliegenden Erfindung werden nachfolgend an Hand einiger Figuren näher erläutert. Es zeigen:

Figur 1 einen Computer und mehrere Peripheriegeräte, welche über eine vom Computergesteuerte Steckdosenleiste mit Strom versorgt werden,

Figur 2 den Aufbau einer mittels USB-Anschluss computergesteuerten Steckdosenleiste und

die Figuren 3 und 4 die Steckbetlegung der einzelnen Pins eines USB-Steckers.

**[0016]** In Figur 1 ist zu sehen, wie das Prinzip einer

über eine Datenschnittstelle gesteuerten Steckdosenleiste 7 aussieht. An einen PC 1 sind über Datenleitungen diverse Peripheriegeräte angeschlossen. Das sind ein Monitor 2, ein Scanner 3 und ein Drucker 4. Da diese Peripheriegeräte 2, 3, 4 einen Netzanschluss aufweisen, müssen sie mit dem Stromnetz verbunden sein. Dazu sind die Peripheriegeräte 2, 3, 4 in die neuartige Steckdosenleiste 7 eingesteckt. Diese wird wiederum von einer herkömmlichen Steckdosenleiste 6 versorgt, über die auch der PC 1 mit Strom versorgt wird. Über einen Netzstecker 5 ist die herkömmliche Steckdosenleiste 6 unmittelbar mit dem Stromnetz verbunden. D.h der PC 1 und die herkömmliche Steckdosenleiste 6 befinden sich in ständiger Verbindung mit dem Netz Die Peripheriegeräte 2, 3, 4 werden nur dann mit Strom versorgt, wenn die neuartige Steckdosenleiste 7 sie zuschaltet. Dies geschieht im einfachsten Fall dadurch, dass der PC 1 eingeschaltet wird Dann liegt an der Datenschnittstelle des PCs 1, hier ein USB-Anschluss, eine Spannung an, welche in der computergesteuerten Steckdosenleiste 7 den Strom zu den Steckdosen 14 der Peripheriegeräte 2,3,4 durchschaltet. Wird der PC 1 wieder ausgeschaltet, wird auch der USB-Anschluss spannungslos, wodurch die Steckdosenleiste 7 abschaltet.

**[0017]** In Figur 2 wird nun der Aufbau einer solchen computergesteuerten Steckdosenleiste 7 näher gezeigt, welcher als Datenübertragungsschnittstelle den USB-Anschluss verwendet. Die Steckdosen 14 für die Peripheriegeräte 2,3,4 sind durch einen Schalter 13 von der Stromzuführung 12 trennbar. Der Schalter 13 wird dabei von einem Schaltungsbauteil 11, USB-Interface genannt, angesteuert. Dieses USB-Interface 11 besitzt ein USB-Anschlusskabel mit einem USB-Stecker 10. Dieser ist an den USB-Anschluss des PCs 1 angeschlossen. Wie die Steckerbelegung eines solchen USB-Steckers 10 aussieht, ist den Figuren 3 und 4 zu entnehmen Die beiden äußeren Pins des Steckers 10 dienen der Stromversorgung angeschlossener Geräte, welche einen geringen Stromverbrauch haben. So kann zB. der Scanner 3 auch direkt über den USB-Anschluss mit Strom versorgt werden. Beim Monitor 2 und beim Drucker 4 ist dies aber nicht möglich, da sie zuviel Strom verbrauchen und die maximale Last am USB-Anschluss 500 mA beträgt. Hier ist auf jeden Fall ein Netzanschluss notwendig. Als Schalter 13 ist ein Relais vorgesehen. Ist nun der PC 1 eingeschaltet, liegt an den beiden äußeren Pins des Steckers 10 eine Spannung an und das Relais schaltet die Steckdosen 14 an die Stromzuführung 12. Nun werden alle Peripheriegeräte 2,3,4 mit Strom versorgt. Wird der PC wieder ausgeschaltet, öffnet das Relais wieder und die Stromversorgung der Steckdosen 14 wird unterbrochen.

**[0018]** Statt eines Relais kann als Schalter 13 aber auch ein Opto-Relais oder ein Halbleiterschalter verwendet werden. Diese benötigen nur einen schwachen Steuerstrom von ca. 10 mA, so dass der USB-Anschluss 10 kaum belastet wird und von einem weiteren

USB-Gerät belastet werden kann. Ist an der Steckdosenleiste 7 ein externer USB-Anschluss vorgesehen, so kann an diesen das weitere USB-Gerät angeschlossen werden, indem das USB-Signal an dieses Gerät durchgeschleift wird

**[0019]** An Stelle des einen externen USB-Anschlusses kann auch ein USB-Hub in die Steckdosenleiste 7 integriert werden, so können mehrere Geräte mit USB-Anschluss angeschlossen werden, wobei die Stromversorgung dann zweckmäßiger Weise über die Steckdosen 14 erfolgt, da über den USB-Anschluss selbst allen Geräten insgesamt nur maximal 500 mA zur Verfügung stehen, was nicht ausreicht. Eine solche Steckdosenleiste 7 stellt eine Datenverteilungszentrale mit Stromversorgungszentrale dar und passt in das leicht modifizierte Gehäuse einer herkömmlichen Steckdosenleiste.

**[0020]** Als Ausbaustufe ist vorgesehen, nicht auf die Betriebsspannung der beiden äußeren Pins des USB-Steckers 10 zurückzugreifen, sondern die USB-Signale selbst zu verwenden. Dazu ist in das USB-Interface 11 ein Decoder für USB-Signale eingebaut. Außerdem sind statt des einen Schalters 13 alle Steckdosen 14 der Steckdosenleiste 7 durch den Decoder separat in Abhängigkeit der USB-Signale schaltbar. Die Steckdosen 14 können nun vom PC 1 aus individuell über eine entsprechende Software ein- und ausgeschaltet werden. So kann zB. gezielt der Drucker 4 nur dann zugeschaltet werden, wenn ein Druckvorgang anliegt. Dies senkt den Stromverbrauch, da sich dann der Drucker 4 nicht im Stand-by Modus befindet, wenn er nicht benötigt wird, sondern komplett ausgeschaltet ist.

**[0021]** Anstatt des im Ausführungsbeispiel verwendeten USB-Anschluss sind auch andere Datenübertragungsschnittstellen wie parallele und serielle Computerschnittstellen oder der IEEE 1394-Anschluss nutzbar.

## Patentansprüche

1. Anordnung zur Stromversorgung von Peripheriegeräten (2, 3, 4) eines elektronischen Geräts (1) mit wenigstens einer Datenübertragungsschnittstelle, wobei die Anordnung wenigstens eine Steckdose (14) und einen Netzanschlusstecker (12) aufweist sowie eine Datenübertragungsschnittstelle (10), welche zur Steuerung des Einschaltens und Ausschaltens der Steckdose (14) vorgesehen ist.
2. Anordnung nach Anspruch 1, **dadurch gekennzeichnet, dass** die Datenübertragungsschnittstelle (10) ein USB-Anschluss ist.
3. Anordnung nach Anspruch 1, **dadurch gekennzeichnet, dass** wenigstens zwei (14) Steckdosen vorhanden

sind, welche unabhängig voneinander über von der Datenschnittstelle (10) übertragene Befehle geschaltet werden können.

4. Anordnung nach Anspruch 1, **dadurch gekennzeichnet, dass** als Schaltelement (13) zum Schalten der Steckdosen (14) ein elektromagnetisches Relais vorgesehen ist.
5. Anordnung nach Anspruch 2, **dadurch gekennzeichnet, dass** als Schaltelement (13) zum Schalten der Steckdosen (14) ein Halbleiterrelais vorgesehen ist.
6. Anordnung nach Anspruch 1, **dadurch gekennzeichnet, dass** vorgesehen ist, dass die Steckdosen (14) gemeinsam eingeschaltet werden, wenn über die Datenschnittstelle (10) ein Strom fließt und gemeinsam ausgeschaltet werden, wenn kein Strom über die Datenschnittstelle (10) fließt.
7. Anordnung nach Anspruch 2, **dadurch gekennzeichnet, dass** diese zusätzlich zum USB-Anschluss (10) wenigstens einen USB-Anschluss zur Datenübertragung an Peripheriegeräte (2, 3, 4) aufweist.
8. Anordnung nach Anspruch 2, **dadurch gekennzeichnet, dass** zusätzlich zum USB-Anschluss (10) ein USB-Hub integriert ist.
9. Anordnung nach Anspruch 8, **dadurch gekennzeichnet, dass** die Datenübertragungsschnittstelle (10) und erforderliche Schaltmittel (11, 13) in eine Mehrfachsteckdosenleiste (7) eingebaut sind.
10. System mit einem elektronischen Gerät (1) und wenigstens einem Peripheriegerät (2, 3, 4), **dadurch gekennzeichnet, dass** vorgesehen ist, das Peripheriegerät (2, 3, 4) über eine Anordnung nach Anspruch 1 mit Strom zu versorgen.

A portable noncontact thermometer comprising a hand-held housing defining an aperture for ingress of incident thermal energy from a target location. A thermometer module including a noncontact thermal energy detector is also provided. The thermometer module further includes at least one microcontroller operative to interpret electrical signals derived from an output of the noncontact thermal energy detector so as to determine temperature at the target location. A USB-HID communication interface is operative to permit electrical communication between the microcontroller(s) and a remote computer. A display device, fixed with respect to the housing, is also provided.

COMMAND LEVEL

## PORTABLE IR THERMOMETER HAVING USB-HID INTERFACE

### BACKGROUND OF THE INVENTION

**[0001]** The present invention relates generally to portable IR thermometers. More particularly, the invention relates to a portable IR thermometer having a USB-HID interface for communication with a common personal computer (PC) in an easily used plug and play manner.

**[0002]** Portable infrared (IR) thermometers allow a user to ascertain the temperature of a remote target using a point and click technique. These instruments are commonly utilized for purposes ranging from automotive diagnostics to food safety. In the past, such instruments have been adapted for connection to a PC so that measured data could be downloaded to the PC via serial connection. In some cases, routes and emissivity data could be uploaded from the PC to the instrument.

**[0003]** Various details regarding the construction and operation of noncontact thermometers may be discerned from U.S. Pat. Nos. 4,634,294, 5,640,015 and 6,234,669, each of which is incorporated herein by reference in its entirety.

### SUMMARY OF THE INVENTION

**[0004]** According to one aspect, the present invention provides a portable noncontact thermometer comprising a hand-held housing defining an aperture for ingress of incident thermal energy from a target location. A thermometer module including a noncontact thermal energy detector is also provided. The thermometer module further includes at least one microcontroller operative to interpret electrical signals derived from an output of the noncontact thermal energy detector so as to determine temperature at the target location. A USB-HID communication interface is operative to permit electrical communication between the microcontroller(s) and a remote computer. A display device, fixed with respect to the housing, is also provided.

**[0005]** In some exemplary embodiments, the communication interface is capable of downloading information from the microcontroller(s) and uploading information to the microcontroller(s). Preferably, the communication interface also permits reprogramming of the microcontroller. Oftentimes, the at least one microcontroller may comprise a main microcontroller and an ADC microcontroller in communication with each other. The ADC microcontroller in such embodiments may be reprogrammed via the main microcontroller. The noncontact thermometer may further comprise a mini-USB port located on the housing and electrically connected to the communication interface.

**[0006]** According to another aspect, the present invention provides a system comprising a portable noncontact thermometer having a USB-HID communication interface. The communication interface of the noncontact thermometer is operative to convert In and Out reports pursuant to HID protocol. A remote computer having an operating system running a USB-HID driver so as to communicate with the thermometer via the communication interface is also provided. Preferably, the system will comprise software running on the computer for downloading temperature information from the noncontact thermometer to the computer and/or uploading emissivity data from the computer to the noncontact thermometer. The communication interface of the noncontact thermometer may be operative to communicate with the remote computer via a wired connection.

**[0007]** Additional aspects of the present invention, including various combinations and subcombinations of the disclosed elements, will be apparent from the remainder of the specification.

### BRIEF DESCRIPTION OF THE DRAWINGS

**[0008]** A full and enabling disclosure of the present invention, including the best mode thereof, to one of ordinary skill in the art, is set forth more particularly in the remainder of the specification, including reference to the accompanying drawings, in which:

**[0009]** FIG. 1 is a perspective view of a portable IR thermometer constructed in accordance with the present invention;

**[0010]** FIG. 2 is a rear view of the thermometer of FIG. 1 showing the graphical display;

**[0011]** FIG. 3 is a diagrammatic representation showing certain internal components of the thermometer of FIG. 1;

**[0012]** FIG. 4 is a diagrammatic representation of the various microcontrollers installed in the thermometer of FIG. 1 according to a preferred embodiment;

**[0013]** FIG. 5 shows a personal computer connected to the thermometer of FIG. 1 via the USB-HID connection;

**[0014]** FIG. 6 is an enlarged view showing the USB connector port of the thermometer shown in FIG. 1;

**[0015]** FIG. 7 is a diagrammatic representation showing the Out report protocol; and

**[0016]** FIG. 8 is a diagrammatic representation showing the In report protocol at command level.

**[0017]** Repeat use of reference characters in the present specification and drawings is intended to represent same or analogous features or elements of the invention.

### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

**[0018]** It is to be understood by one of ordinary skill in the art that the present discussion is a description of exemplary embodiments only, and is not intended as limiting the broader aspects of the present invention, which broader aspects are embodied in the exemplary constructions.

**[0019]** FIGS. 1 and 2 illustrate an exemplary hand-held thermometer 10 in accordance with principles of the present invention. Thermometer 10 includes an internal detector which collects energy radiated from a selected target. The energy, typically in the form of infrared (IR) radiation, is isolated and focused on the detector. The detector converts the energy into an electrical signal which is then internally processed to yield a temperature value.

**[0020]** As shown, thermometer 10 includes a housing 12 in which various internal components are located. While any suitable material can be utilized, housing 12 is preferably formed of a rigid high impact plastic material. As shown, housing 12 includes a handle 14 on which a trigger 16 is located. Activating trigger 16 puts the thermometer in a "scan" (or active measurement) mode. A laser diode may be provided to project a dot of light forward of the thermometer to facilitate aiming.

**[0021]** As indicated at 18, a graphical display device is preferably located at the rear of thermometer 10. In this case, a variety of information is shown on display device 18, including a reading of the target temperature. The target temperature (234.5° F. in FIG. 2) is preferably shown in large font

in the center of the screen. Various functions of thermometer 10 are controlled by buttons 20, 22 and 24.

[0022] Preferably, thermometer 10 is configured to implement a graphical user interface (GUI) on display device 18. As shown in FIG. 2, for example, three tabs are located at the bottom of the screen in regions corresponding to buttons 20, 22 and 24, respectively. In this case, the respective tabs contain the words "Save," "Menu" and "Light" as indicators of the function that may be performed by pressing the corresponding button. These functions may change depending on where a particular screen appears in the GUI menu tree. Various icons may also be displayed on the screen.

[0023] Certain internal components of thermometer 10 will be explained with reference to FIG. 3. Thermal energy from a selected target passes through an aperture 26 defined in housing 12, where it is directed by optics to an IR detector 28. The output of detector 28 is fed to an amplifier 30, and then to analog-to-digital converter (ADC) 32. In this case, ADC 32 is implemented using a microcontroller having a high-resolution A/D converter. The resulting digital signal from ADC 32 is then fed to main microcontroller (MCU) 34. Microcontroller 34 utilizes preprogrammed algorithms to convert the digital detector data into temperature information. A memory 36 (which may be internal to microcontroller 34) stores temperature information, along with firmware and other information (such as emissivity) utilized during operation. Detector 28 along with its associated circuitry (e.g., amplifier 30, ADC 32, main microcontroller 34 and memory 36) can be thought of collectively as a thermometer module (whether or not they form a single physical unit). In some embodiments, the thermometer module may further include an ambient temperature sensor 38. The function buttons 20, 22 and 24 are collectively indicated at 40.

[0024] As shown, display device 18 is in electrical communication with microcontroller 34. Preferably, display device 18 may be configured as a dot matrix or other suitable graphical display which implements the GUI. For example, display device 18 may be a 98×96 pixel LCD dot matrix display in some presently preferred embodiments. As a result, complex functions can be implemented with a minimum of control buttons and the user can be guided towards selecting functions and inputting parameters to the thermometer. In addition, the graphical display allows for flexible display of data and inputs, and can be customized for language, font size and the like. Different operating modes can also have different screen appearances. In this embodiment, the GUI is run on main microcontroller 34 (as indicated at 42).

[0025] It is desirable for a noncontact thermometer to have a connection to a PC so that data can be transferred between the instrument and the PC. In this case, a controller 43 installed in thermometer 10 permits communication with a common PC 44 using a driver already included within the PC's operating system. In particular, PCs running the common Windows operating system (since at least Windows 98) include a driver (schematically indicated at 46) for communicating with a Human Interface Device (HID), such as a keyboard or mouse, using the PC's universal serial bus (USB). In accordance with the present invention, it has been found that USB-HID protocol may be utilized with a noncontact thermometer instrument for "plug and play" convenience and ease of use. The USB-HID interface permits download of measured data, as well as upload of routes and emissivity information. Updates to the instrument's firmware and calibration can also be easily accomplished in the field.

[0026] Referring now also to FIG. 4, certain additional aspects of the communication interface can be most easily explained. While embodiments are contemplated in which a single microcontroller fulfills all functional needs of the instrument, the present invention utilizes three microcontrollers 32, 34 and 43. As indicated at 46, USB microcontroller 43 includes a hardware USB interface or a USB interface implemented in software. In particular, the interface functions to provide "In" or "Out" reports by way of data exchange in the manner used by USB-HID interfaces. In this case, for example, USB controller 43 may be a CY7C63813 controller available from Cypress Semiconductors.

[0027] As noted above, ADC 32 may take the form of a microcontroller having a high resolution A/D converter. One chip suitable for this purpose is MSP430F20x3 available from Texas Instruments. While this device has an excellent A/D converter, it has limited onboard memory. Additional memory, however, may be desirable in instrument 10 to implement the GUI, as well as a sophisticated temperature calculation algorithm, etc. This additional memory and processing capability may be provided by main microcontroller 34, which may be a MSP430F1491 chip in some exemplary embodiments. This device is also available from Texas Instruments.

[0028] During normal operations, digital data produced by ADC 32 is fed to main microcontroller 34 along line 48. In this embodiment, main microcontroller 34 implements a SPI master interface, whereas a SPI slave interface is implemented on ADC 32. Similarly, data transfer between USB controller 43 and main microcontroller 34 occurs along line 50. In this regard, USB controller 43 implements a SPI master interface, whereas a SPI slave interface is implemented on main microcontroller 34. Thus, temperature data as calculated by main microcontroller 34 may be provided to USB controller 43 along line 50 for transfer to the remote computer. Likewise, route information and emissivity tables can be transferred from the PC to main microcontroller 34 along line 50.

[0029] Flash memory in ADC 32 and main microcontroller 34 may be reprogrammed using the USB-HID interface. In this case, for example, controller 43 runs software implementing a universal asynchronous receiver transmitter (UART) which is in communication with a "bootstrap" (i.e., hardware) UART of main microcontroller 34 via line 52. This line may be utilized to replace firmware and calibration data in the flash memory of main microcontroller 34. If this flash memory requires special protocols to be programmed, then the USB-HID controller implements the required protocols and converts the "In" and "Out" reports into the datastream required by the flash ROM programming protocols. For example, new firmware can be provided for debugging purposes, as well as to add additional functions to the instrument.

[0030] In this exemplary case, ADC 32 is not equipped with a UART interface, so it may be reprogrammed using a "spy-bi-wire" interface. In one preferred embodiment, for example, a spy-bi-wire master interface is implemented (such as by software) on main microcontroller 34 which communicates with a spy-bi-wire slave interface (via line 54) implemented on ADC 32. In this manner, main microcontroller 34 functions as an intermediary between USB controller 43 and ADC 32 for programming purposes. Alternatively, a spy-bi-wire master interface may be implemented on USB controller 43, which communicates directly with the spy-bi-wire slave interface of ADC 32, as indicated at 56.

[0031] In the illustrated embodiments, in which main microcontroller 34 functions as a programming intermediary, the following steps may be implemented during the reprogramming process: (1) Existing firmware in main microcontroller 34 is deleted. (2) The firmware in main microcontroller 34 is then reprogrammed via USB controller 43 so that main microcontroller 34 can be used to reprogram ADC 32. (3) ADC 32 is then reprogrammed. (4) Next, the original (or updated) firmware in main microcontroller 34 is replaced.

[0032] FIG. 5 shows thermometer 10 in electrical communication with a conventional personal computer 44. As one skilled in the art will appreciate, the term “computer” as used herein is not limited to a traditional desktop or laptop personal computer. Instead, “computer” is included to cover other devices, such as various personal digital assistants (PDAs), that may be capable of performing the described functionality. In this embodiment, however, computer 44 is a traditional desktop personal computer having a main housing 60 containing processing electronics, disk drives and the like. A suitable computer display 62, in this case an LCD flat screen display, is also provided. The user interacts with computer 44 using keyboard 64 and mouse 66 in the conventional manner.

[0033] The invention contemplates various techniques for providing a data link between thermometer 10 and computer 44, such as various wireless communication protocols. In the illustrated embodiment, however, electrical communication between thermometer 10 and computer 44 is accomplished using a typical serial cable 68. Cable 68 includes universal serial bus (USB) connectors at each end, one of which plugs into a corresponding port on the front of housing 60 (as indicated at 70).

[0034] As can be most clearly seen in FIG. 6, the other connector 72 is configured as a mini-USB connector. Connector 72 is inserted into a corresponding port 74 located on the top of thermometer 10. In this embodiment, a receptacle 76 is located adjacent to mini-USB port 74 for connecting a thermocouple probe for contact measurements. Computer 44 preferably includes application software which creates a user interface for displaying temperature data, logged data sets, allows editing routes and emissivity tables, and supports firmware and calibration data updates in the field. The PC application converts the data streams, required for such functions, into “In” and “Out” reports, which are used for data exchange pursuant to USB-IIID protocol.

[0035] FIGS. 7 and 8 show the format of the “In” and “Out” reports in accordance with a preferred embodiment. All data transfers are in binary.

#### Host to Device Data Transfer

[0036] The host sends command and data to the device.

[0037] Data transferring from the host to the device is through USB Control.

[0038] Out Report (FIG. 7)

[0039] A transfer reside in one or more USB Data Packet. According to USB Low Speed specification, each Data Packet is 8-byte long.

[0040] As shown in FIG. 7, at Packet Level each packet contains a Cnt.

[0041] At Command Level, each transfer has Cmd, Len, Data, and Zeros. At Command Level, a transfer can be of any length.

Packet Level			
Cnt	1 byte	Bit 7	Reset
			0 Continued packet to the previous packet in a transfer.
			1 First packet in a transfer
		Bit 6-0	7-bit counter. Increases by one for each packet and wraps to 0. In this way, a lost packet can be detected.
			A discontinuous value indicates a transfer error.
			0-127
Command Level			
Cmd	1 bytes	Command code. 1~127. 0 is reserved for heading zero. 128~255 is reserved for protocol extension.	
Len	2 bytes	The byte length of this transfer. The length includes Cmd, Len and all Data parts in this command, but does not include any Cnt or the zeros part. Low byte first. 3~65535.	
Data	Variable bytes	Data of this command. 0 bytes minimum. 65532 bytes Maximum.	
Zeros	Variable bytes	0s added at the end of the last packet to make all packet 8-byte length. 0 bytes minimum. 6 bytes maximum.	

[0042] Every command transaction is preferably followed by one Device to Host Data Transfer at the minimum acknowledge receipt and validation of the transmitted Host Data to Device transfer.

[0043] Device to Host Data Transfer

[0044] The device sends data to the host as a response to the host command. Data transferring from the device to the host is through USB Interrupt In Report.

Packet Level			
Same as Host to Device Transfer, a Device to Host Transfer resides in one or more USB Data Packet. Each Data Packet is 8-byte long.			
Cnt	1 byte	Bit 7	Reset
			0 Continued packet to the previous packet in a transfer or
			1 First packet in a transfer
		Bit 6-0	7-bit counter. Reference to as described above under Host to Device Data Transfer.
			As a response to a previous Host to Device Transfer, the counter in the first packet sent by the Device is one more than that of the previous packet sent by the Host with
			Reset bit has a value of 1.
			0-127
Command Level (FIG. 8)			
cAck	1 bytes	If command was valid cAck = 30 (ASCII char ‘0’)	
		If the command was not valid/acted on, a value should be between 31 and 39 Command code.	
		0 Reserved for heading zeros	
		1-127 Acknowledge code	
		128-255 Reserved for protocol extension	
Len	2 bytes	The byte length of this transfer. The length includes Cmd, Len and all Data parts in this command, but does not include any Cnt or the zeros part. Low byte first. 3~65535.	
Data	Variable bytes	Data to transfer. 0 bytes minimum. 65532 bytes Maximum.	
Zeros	Variable bytes	0s added at the end of the last packet to make all packet 8-byte length. 0 bytes minimum. 6 bytes maximum.	

[0045] It can thus be seen that the present invention provides a portable IR thermometer having a USB-HID interface. While preferred embodiments of the invention have been shown and described, modifications and variations may be made thereto by those of ordinary skill in the art without departing from the spirit and scope of the present invention. In addition, it should be understood that aspects of the various embodiments may be interchanged both in whole or in part. Furthermore, those of ordinary skill in the art will appreciate that the foregoing description is by way of example only, and is not intended to be limitative of the invention as further described in the appended claims.

What is claimed is:

1. A portable noncontact thermometer comprising:
  - a hand-held housing defining an aperture for ingress of incident thermal energy from a target location;
  - a thermometer module including a noncontact thermal energy detector;
  - said thermometer module further including at least one microcontroller operative to interpret electrical signals derived from an output of said noncontact thermal energy detector so as to determine temperature at said target location;
  - a USB-HID communication interface operative to permit electrical communication between said at least one microcontroller and a remote computer; and
  - a display device fixed with respect to said housing.
2. A portable noncontact thermometer as set forth in claim 1, wherein said communication interface is capable of downloading information from said at least one microcontroller and uploading information to said at least one microcontroller.

3. A portable noncontact thermometer as set forth in claim 1, wherein said communication interface permits reprogramming of said at least one microcontroller.

4. A portable noncontact thermometer as set forth in claim 3, wherein said at least one microcontroller comprises a main microcontroller and an ADC microcontroller in communication with each other.

5. A portable noncontact thermometer as set forth in claim 4, wherein said ADC microcontroller is reprogrammed via main microcontroller.

6. A portable noncontact thermometer as set forth in claim 1, comprising a mini-USB port located on said housing, said mini-USB port being electrically connected to said communication interface.

7. A system comprising:

- a portable noncontact thermometer having a USB-HID communication interface, said communication interface being operative to convert in and out reports pursuant to HID protocol; and

- a remote computer having an operating system running a USB-HID driver so as to communicate with said thermometer via said communication interface.

8. A system as set forth in claim 7, further comprising software running on said computer for downloading temperature information from said noncontact thermometer to said computer.

9. A system as set forth in claim 7, further comprising software running on said computer for uploading emissivity data from said computer to said noncontact thermometer.

10. A system as set forth in claim 7, wherein said communication interface of said noncontact thermometer is operative to communicate with said remote computer via a wired connection.

### [57] ABSTRACT

A method and apparatus by which an operator without Chinese cooking skills or knowledge can cook consistent, superior Chinese stir-fry dishes with higher productivity and with a wider repertoire of recipes than that of the traditional Chinese chef. This invention includes means for entering and storing recipe data in a computer control system, means for selecting a recipe from a displayed menu, and means for cooking the selected recipe automatically by the computer control system including addition of food and liquid ingredients at proper intervals, temperature control throughout the cooking process, stirring of the cooking food, and timing of the cooking process, all according to the recipe selected.

## METHOD AND APPARATUS FOR AUTOMATED CHINESE STIR-FRY COOKING

### BACKGROUND OF THE INVENTION

This invention relates to Chinese cooking and specifically to a method and apparatus that a restaurant might use for automated Chinese stir-fry cooking which does not require the operator to possess knowledge or skills in the art of Chinese stir-fry cooking. This invention incorporates steps including entering and storing recipe data, selection of a recipe from a menu, addition of food and liquid ingredients at the proper intervals, temperature control throughout the cooking process, stirring of the cooking food, and timing of the cooking process, all performed automatically by a computer control system.

### DESCRIPTION OF PRIOR ART

Chinese stir-fry cooking is the brisk cooking of small cuts of meats and vegetables in hot oil over intense heat, calling for split-second timing and swift movements in an uninterrupted rhythm. It is the most common method of cooking Chinese food and means literally "toss-cooked". Two elements are crucial to stir-frying. Firstly, thorough organization, in the sense that everything needed is within reach so no interruption will disturb the cooking once it starts; and secondly, vigilance from the chef who must be ready to measure and add ingredients, and adjust timing and volume of heat instantly. Each dish is allowed to cook for only one to four minutes. This cooking process requires considerable skill with the chef judging the progress of the dish by the smell, look and feel of the food and the sound of the cooking. Each order is cooked individually. At the completion of the cooking process, the chef scoops the cooked food onto a serving dish, cleans the cooking pan, and prepares to cook the next order. Because of the required knowledge and skill, many Chinese chefs begin their training at a young age and specialize in a regional style of cooking such as Cantonese or Szechwanese. Virtually all Chinese restaurants are operated by Chinese families who compete for the good chefs. J. B. Bakos, Editor of the trade magazine *Restaurant Business*, has written: "It is interesting to note that we have not seen the development of a Chinese restaurant chain". One reason for this is that a good Chinese restaurant is dependent on its chef, and a chef's span of control rarely exceeds one restaurant. Were there a way to capture and multiply the knowledge and the skills of a good Chinese chef, a whole new opportunity would be created for expansion in the Chinese restaurant industry.

### BRIEF SUMMARY OF THE INVENTION

Accordingly, several objects of this invention are: (1) to provide a method and apparatus by which an operator without Chinese cooking skills or knowledge can cook consistent, superior Chinese stir-fry dishes, (2) to increase the level of productivity over that of even the skilled Chinese chef by allowing the operator of this invention to cook several dishes concurrently, (3) to provide for cooking a wider range of regional stir-fry dishes than is commonly found in the repertoire of the traditional Chinese chef, to include the styles of Canton, Hunan, Peking, Shanghai and Szechwan. Further objects and advantages of this invention will become ap-

parent from a consideration of the drawings and descriptions which follow.

The method and apparatus of this invention include the following interrelated components:

- (a) a Chinese stove with gas burner;
- (b) a wok with means for rotation about its vertical axis during the cooking process; as used in this description and in the appended claims, the term "wok" means a bowl-shaped cooking pan;
- (c) a food tray with a rotatable divider for holding and dispensing food ingredients into the wok in predetermined time sequences;
- (d) a spatula with driving means for stirring and tossing the food as it cooks;
- (e) a plurality of liquid dispensers for holding and dispensing liquid ingredients into the wok in predetermined quantities and in predetermined time sequences;
- (f) a temperature measuring component for measuring the temperature of the wok throughout the cooking process;
- (g) a gas valve for controlling a supply of gas to the gas burner;
- (h) a computer control system for storing, displaying and processing recipe information, for activating and deactivating the means to rotate the wok, the means to drive the spatula, the means to rotate the rotatable divider of the food tray, for activating and deactivating the plurality of liquid dispensers, for activating and deactivating the gas valve, and for receiving temperature measurements from the temperature measuring component.

The method and apparatus of this invention performs the entire cooking process automatically. The operator selects a recipe from a displayed menu, mounts a corresponding food tray, and presses a "start" key. When the cooking is complete, the operator scoops the food onto a serving dish, replaces the wok and spatula with clean utensils, and is ready to repeat the process for the next order. The computer control system under program instructions heats the wok, adds and stirs the food, times the cooking, measures and adds liquid ingredients and regulates the heat, all according to the recipe selected. The computer control system accommodates a multiplicity of recipes each of which may be individually varied by the person preparing the recipes. New recipes may be added to the computer control system using a straightforward cookbook notation. Furthermore, by operating several of these inventions, a single operator may cook several orders concurrently.

### BRIEF DESCRIPTION OF THE DRAWINGS

For an illustration of the construction and operation of the preferred embodiment, reference is made to the attached several views wherein identical reference numbers are utilized to refer to identical or equivalent components throughout the several views.

FIG. 1 is a front elevation view of the overall assembly.

FIG. 2 is a side elevation view of the spatula with driving means for stirring and tossing the food as it cooks.

FIG. 3 is a side elevation view of the food tray with rotatable divider for holding and dispensing food ingredients into the wok.

FIG. 4 is a side elevation view of the plurality of liquid dispensers for holding and dispensing liquid ingredients into the wok.

FIG. 5 is a side elevation view of the wok with means for rotation about a vertical axis, and the temperature measuring component for measuring the temperature of the wok.

FIG. 6 is a "filled-out" recipe worksheet used for preparing a recipe to be entered into the computer control system.

FIG. 7 and FIG. 8 are program structure flowcharts illustrating the program logic of the computer control system.

FIG. 9 is a schematic diagram of the computer control system interface.

### DESCRIPTION OF THE PREFERRED EMBODIMENT

For a description of the construction and utilization of this method and apparatus, reference is made to the attached drawings. This applicant has constructed, tested and extensively experimented with a fully operational prototype of this invention in his kitchen at home.

The construction of the apparatus begins with a conventional Chinese stove 8 of FIG. 1 as used in Chinese restaurants and a wok 9 of FIGS. 1 and 5. In conventional usage of the Chinese stove, the wok is stationary over a gas burner 10. A Chinese chef controls the heat by a manual gas valve 52. The air and gas mixture to the gas burner is adjustable by two air/gas mixture valves 51. In the apparatus of this invention the wok rests on a metal collar 11 rotatably supported over the gas burner. The collar is operably attached to the top of a vertical pipe 12. The vertical pipe passes downward through the center of the gas burner 10, and is rotatably supported beneath the gas burner by a ball bearing pillow block 13. The ball bearing pillow block is operably mounted to the framework 14 of the Chinese stove. A first motor means 15, operably coupled to the vertical pipe, rotates the vertical pipe thereby rotating the collar and the wok. The first motor means is activated and deactivated by signals from a computer control system to be subsequently described.

A food dispensing component illustrated in FIG. 3, is comprised of a food tray 16, a rotatable divider 17 which fits in the food tray and which partitions the food tray into a plurality of compartments 18, a tray arm 19 which projects horizontally over the wok, a first base 20 which supports the tray arm, a tray spindle 21 rotatably mounted vertically on the tray arm over the wok, a second motor means 22 operably mounted on the first base, a first driving means 23 which operably couples the second motor means to the tray spindle. The food tray is comprised of a round pan with bottom means having a hole in the center thereof and a sector-shaped opening thereof 24. The rotatable divider is comprised of a plurality of panels 25 which radiate outward from a hub 26. A keyed mounting ring 27 is operably attached to the bottom of the hub. The tray spindle has a keyed tip matching the keyed mounting ring. The food tray containing the rotatable divider is removably mounted upright on the tray spindle by the operator with the tray spindle fitting through the hole in the bottom means of the food tray and into the keyed mounting ring on the bottom of the hub of the rotatable divider. The second motor means is activated by signals from the computer control system.

When activated, the second motor means rotates the first driving means to rotate the tray spindle thereby turning the rotatable divider. This rotation moves the food ingredients, in the compartment adjacent to the

sector-shaped opening in the food tray, over the sector-shaped opening where, by gravity, the food ingredients fall into the wok. The amount of rotation is a predetermined quantity programmed in the computer control system. At the end of the predetermined rotation the computer control system deactivates the second motor means. This allows the food ingredients in each compartment to be dispensed into the wok in a predetermined sequence and in predetermined intervals by signals from the computer control system. A further detail of the food tray is a catch means 28 operably attached to the food tray which engages a stop means 29 operably attached to the tray arm when the food tray with rotatable divider is mounted on the tray spindle. This prevents the food tray from turning when the rotatable divider turns.

The components for stirring the food and liquid ingredients, illustrated in FIG. 2, is comprised of a spatula 30 with a blade 31 and a handle 32, a spatula arm 33, a vertical reciprocating linear motion means 34, a third motor means 35, a second base 36 on which the third motor means is mounted, a second driving means 37 for coupling the third motor means to the vertical reciprocating linear motion means, a cam 38, a rotatable cam rod 39, a cam rod support means 40, a third driving means 41 for coupling the cam to the third motor means. The spatula is removably connected pivotally at the handle to the spatula arm. The spatula arm is operably attached to the vertical reciprocating linear motion means. The vertical reciprocating linear motion means is operably coupled to the second driving means. The second driving means is operably coupled to the third motor means. This coupling converts the rotary motion of the third motor means to a vertical reciprocating linear motion of the spatula arm. On the downward motion of the spatula arm the blade of the spatula sweeps down the inside surface of the wok until reaching just past bottom center of the wok. The blade of the spatula is biased against the inside surface of the wok by a spring means 42 operably attached removably to the handle of the spatula and operably attached to the other end to the spatula arm. When the blade of the spatula reaches just past bottom center of the wok the movement of the spatula arm reverses direction and draws the blade of the spatula back to its initial position at the inside edge of the wok.

As the blade of the spatula is drawn back, the cam, positioned directly beneath the spatula handle, rotates to make contact with the spatula handle. On contact, the cam lifts the spatula up from the inside surface of the wok as the spatula is drawn back. With the wok rotating, the motion of the spatula blade stirs and tosses the food and liquid ingredients from all sides of the wok. Further details of the cam are as follows. The cam is operably mounted perpendicularly to the end of the cam rod. The cam rod is rotatably mounted operably to the cam rod support means. The cam rod is operably attached to the third driving means. The third driving means is operably coupled to the third motor means. The third driving means transmits a counterclockwise rotary motion of the third motor means to clockwise rotary motion of the cam. The motion of the cam is synchronized with the motion of the spatula arm since both the cam and the spatula arm are driven by the same third motor means. The third motor means is activated and deactivated by signals from the computer control system.

The liquid dispensing component illustrated in FIG. 4, is comprised of a plurality of identical liquid dispensers each comprised of a bulk container 1 to hold the liquid, a length of hose 2 operably attached to an outlet means on each bulk container, a pinch valve 3 installed on each length of hose so that the flow of liquid is controlled by the pinch valve; a horizontal rack to support the pinch valves 4, a funnel means 6, a third base 5 to support the horizontal rack and the funnel means, and a fourth base 7 to support the bulk containers. The individual pinch valves are electrically activated (to open) and deactivated (to close) by signals from the computer control system. The pinch valves are operably mounted on the horizontal rack which is operably mounted on the third base. The discharging ends of the hoses converge into the funnel means. The funnel means is mounted on the third base with the spout of the funnel means pointing into the wok. The bulk containers, holding liquid ingredients such as soy sauce, chicken broth, cooking oil and the like, are mounted on the fourth base which is operably attached to the back of the Chinese stove.

When a pinch valve is activated, gravity feed produces a flow of the respective liquid which passes downward through the respective hose through the funnel means and into the wok. The length of time a pinch valve is opened is calculated by the computer control system to dispense a desired quantity of the respective liquid. Through extensive experimentation mathematical equations for flow rates for each liquid have been derived and programmed into the computer control system. These equations allow a recipe specification of one teaspoon of soy sauce, for example, to be converted to a time interval for which the respective pinch valve is to remain open in order to dispense one teaspoon of soy sauce. These equations are shown in lines 4070-4130 of the computer program listing which is subsequently presented. Although gravity feed is employed in this applicant's prototype, it is apparent that pressurization of the liquid containers could be used to increase the flow rates. It is also apparent that food-grade micropumps and corresponding control means could be substituted for the pinch valves to meter precise quantities of the various liquids.

The temperature measuring component, illustrated in FIG. 5, is comprised of a temperature sensor 43 for sensing the temperature of the wok, a digital thermometer 44 with BCD output for converting electrical signals from the temperature sensor to temperature measurements for input to the computer control system, a thermocouple protection tube 45, a sensor support means 46 for supporting the temperature sensor and thermocouple protection tube, and a fifth base 47 for supporting the sensor support means. The thermocouple protection tube is positioned inside the vertical pipe 12. The temperature sensor fits inside the thermocouple protection tube thereby insulating the temperature sensor from the vertical pipe in the region around the intense heat of the gas burner. The temperature sensor and the thermocouple protection tube are operably attached to the sensor support means. The tip of the temperature sensor extends upward through the thermocouple protection tube to touch the bottom surface of the wok. Electrical leads of the temperature sensor extend downward through the thermocouple protection tube and into the sensor support means. The electrical leads emerge from the sensor support means and travel beneath the Chinese stove to the digital thermometer

located near the computer control system. The sensor support means fits into a hole in the fifth base. A spring means 42 in the hole of the fifth base biases the sensor support means upwardly thereby biasing the tip of the temperature sensor against the bottom of the wok.

The gas valve component is comprised of a gas valve 48 of FIG. 1, electrically operated, operably installed in the gas burner supply line of the Chinese stove downstream of the supply branch to the pilot light. The gas valve is activated (to open) and deactivated (to close) by signals from the computer control system. In the deactivated position only the pilot light is on. In the activated position a full flow of gas is supplied to the gas burner from the supply source. As a matter of safety, when the computer control system activates the gas valve the computer control system checks for an immediate increase in temperature of the wok. If this temperature increase does not occur within a few seconds the computer control system deactivates the gas valve and displays a message to the operator to check the pilot light.

The computer control system component is comprised of a general purpose digital microcomputer system 50 with a minimum of 16000 bytes of memory, a programming language BASIC, a video display monitor, a data storage means, a data entry keyboard, an electronic interface 49 which by computer generated signals activates and deactivates the means to rotate the wok, the means to drive the spatula, the means to rotate the rotatable divider of the food tray, activates and deactivates the plurality of liquid dispensers, activates and deactivates the gas valve, and receives the temperature measurements from the digital thermometer. A schematic diagram of the electronic interface is shown in FIG. 9. The numbers with slashes on the lines connecting the components in the diagram indicate the number of wires connecting those components. When no number is given one wire may be assumed.

Activation and deactivation of the respective first, second and third motor means, the gas valve and the plurality of pinch valves is achieved by a program instruction in BASIC: "OUT, port, value". This instruction outputs a byte value to a specified computer port and generates a write command. The byte value contains an address of the device to be selected and a bit pattern which indicates whether the device is to be activated or deactivated. When the computer control system interface receives a write command and a valid address from the computer, it decodes the address and routes the 5 low-order bits on the computer data bus to the device decode and select logic. The device decode and select logic decodes the 5 low-order bits and activates or deactivates the selected device. Temperature measurements of the wok are input to the computer control system by a program instruction in BASIC: "INP, port". This instruction inputs a byte value from the specified computer port and generates a read command. Four of these instructions are utilized under program instructions to input a temperature measurement. The first and second INP instructions input a status indicator from the digital thermometer. When the status indicator shows that the temperature measurement is latched on the computer data bus, the third and fourth INP instructions input the low and high order bits of the 15 bit temperature measurement. When the computer control system interface receives a read command and a valid address from the computer, it decodes the address and then reads the temperature status or the tempera-

ture measurement respectively from the digital thermometer.

The computer control system is further comprised of program instructions to store and process recipe data, to display a menu to the operator, to accept a selection from the menu, and to activate and deactivate the above components to cook the menu selection. The computer control system interface is constructed using conven-

tional techniques for digital circuit logic and commercially available components. A program structure flow-chart is shown in FIGS. 7 and 8. The number in the upper right corner of each box refers to the beginning line number in the computer program for the respective subroutine. Following is the source listing of the entire computer program according to this invention.

#### METHOD AND OPERATION OF THE DEVICE

In the utilization and operation of this invention, the bulk containers are filled with one cup to several quarts, depending on the expected number of orders to be prepared, of soy sauce, chicken broth, cooking oil, sherry, liquid corn starch, oyster sauce, sesame oil, etc. In a priming step performed once each day, each normally deactivated pinch valve is briefly activated to allow the respective liquid to flow into the respective hose forcing out the air in the hose between the bulk container and the pinch valve. To do this the operator, prompted by a message on the video display monitor, presses a key on the computer keyboard. Next, the operator, prompted by a message on the video display monitor, enters the ambient temperature of the cooking oil. This data is used by the computer control system in calculating the flow rate for the cooking oil since the flow rate is temperature dependent. At the completion of these steps, a menu is presented to the operator on the video display monitor. When an order is to be cooked, the operator selects a corresponding food tray marked with the name of the menu selection ordered and containing the precut food ingredients for that recipe. The operator mounts the food tray on the tray spindle, types the number of the menu selection on the computer keyboard, visually confirms the name of the recipe which is displayed and presses the Y key on the keyboard to start the automatic cooking. The operator is now free to initiate another order on another device of this invention. The computer control system activates the normally deactivated gas valve, igniting the gas burner and heating the wok. Temperature measurements of the wok are continually read from the digital thermometer by the computer control system. When the gas burner has heated the wok to the cooking temperature specified in the recipe the computer control system activates the normally deactivated first motor means which initiates rotation of the wok. The computer control system then activates the corresponding pinch valve to dispense cooking oil in the quantity specified for this recipe. Next, the computer control system activates the normally deactivated third motor means which initiates the stirring action of the spatula. After a few seconds, to allow the cooking oil to heat, the computer control system activates the normally deactivated second motor means to rotate the rotatable divider of the food tray to add the first food ingredient and then deactivates the second motor means. At subsequent precisely timed intervals, specified by the recipe, the computer control system rotates the rotatable divider of the food tray as above to add additional food ingredients. Additionally, the computer control system activates appropriate pinch valves to add liquid ingredients at precisely time intervals and in the precise quantities as specified in the recipe. Throughout the cooking process temperature measurements are checked approximately once every one and a half seconds to insure the proper cooking temperature is being maintained. If the temperature should rise too high, that is, if it reaches the upper limit

of an allowable range, the computer control system deactivates the gas valve until the temperature drops to the lower limit of the allowable range, at which time the computer control system again activates the gas valve to turn on the gas burner. The allowable temperature range is plus or minus 3% of the temperature specified in the recipe. For example, a cooking temperature of 350° F. has an allowable range of 340° F. to 360° F. At the completion of the specified cooking time, the computer control system deactivates the first and third motor means which stops the wok rotation and the stirring action of the spatula, and deactivates the gas valve which turns off the gas burner. This signals the operator that the food is done at which time the operator scoops the food onto a dish for serving. The operator then removes the spatula and the wok and replaces them with a clean spatula and wok. The menu is automatically redisplayed on the video display monitor and the apparatus is ready to cook the next order. Although the computer program of this applicant's prototype employs a technique of counting computer cycles of known duration to determine the number of elapsed seconds for timing purposes, it is apparent that a real time clock with appropriate interface means to the computer control system could be used for precise timing control.

The method and apparatus of this invention has extreme versatility for cooking virtually any stir-fry recipe from virtually any Chinese school of cooking. Any desired food ingredients or combination of food ingredients can be added in any chosen sequence at any chosen time interval in the cooking process. Likewise, any liquid ingredient or combination of liquid ingredients can be precisely measured and added in any chosen sequence at any chosen time intervals. Furthermore, the cooking temperature can be repeatedly changed during the cooking process at any chosen time interval. The program instructions of the computer control system are designed to allow easy entry and modification of recipes. The number of recipes that can be stored is limited only by the amount of computer memory available. It is anticipated that a restaurant user of this invention might utilize anywhere from a dozen recipes to 300 or more.

To enter a new recipe the person preparing the recipe first writes the recipe on a recipe worksheet. A sample filled out recipe worksheet is shown in FIG. 6. Using the abbreviations shown at the bottom of the recipe worksheet the person lists the name of the recipe, the initial cooking temperature and then lists the food and liquid ingredients of the recipe in the sequence in which they are to be added. For each food ingredient, the person lists the cooking time desired prior to adding the next ingredient. For each liquid ingredient the person lists the quantity of the liquid ingredient to be added and the desired cooking time prior to adding the next ingredient. The person also lists any changes in cooking temperature desired for the recipe in the sequence desired. This is the essential recipe information that would be described in any Chinese cookbook.

The recipe information is then keyed from the recipe worksheet into the computer program by the person preparing the recipe. Each line is entered as a DATA statement beginning with the next available line number. For example, in the program listing, DATA statements containing recipe information occupy lines 1 to 625. Therefore, a new recipe could be entered beginning at line 626. When all recipe changes or additions have been entered, the person also updates line 1 containing the total number of recipes. If line 1 previously showed "75" recipes and 4 new recipes were entered, this line would be changed to "79". New or revised recipes are permanently stored for immediate or later use.

The components of this invention taken individually are not considered to be the particular novel portion of this invention. The novelty is believed to reside in the combined use of the components to achieve a result not anticipated by the prior art, namely, the ability of an unskilled operator to cook superior Chinese stir-fry food, and to do so with higher productivity and with a larger repertoire of multiregional recipes than the skilled traditional Chinese chef.

I claim:

1. A system for controlling the operation of a stir-fry cooking apparatus comprising:

a rotatable food container means for holding liquid and solid foods to be cooked;  
means for rotating the food container means;  
heating means positioned beneath the food container means;

a plurality of food dispensing means for dispensing liquid and solid foods into the container means;  
stirring manipulator means for stirring the foods in the food container means;

first memory means for storing a plurality of recipe data;

second memory means for storing program data for operating the heating means, the food dispensing means, and the stirring manipulator means;

input means, connected to the first and second memory means, for inputting the recipe data into the first memory means and the program data into the second memory means;

digital processing means, connected to the first and second memory means and the input means for controlling the operation of the heating means, the food dispensing means and the stirring manipulator means in accordance with selected recipe requirements and the program data corresponding to the selected recipe requirements stored in the first and second memories respectively.

2. An apparatus according to claim 1, further comprising:

a display means, connected to the first and second memory means, the input means, and the digital processing means, including means for displaying data to be input to the first memory means and means for displaying the recipe selected from the first memory means.

3. An apparatus according to claim 1, wherein each recipe stored in the first memory means includes a plurality of cooking temperatures, a plurality of liquid and solid food ingredients, and a cooking time for each food.

4. An apparatus according to claim 1, wherein the digital processing means includes:

means for electrically activating and deactivating the heating means;

means for measuring a sensed temperature of the food container means and comparing the sensed temperature with a selected temperature set forth in a selected recipe;

means for causing the sensed temperature to become equal to the selected recipe temperature.

5. An apparatus according to claim 1, wherein the digital processing means includes:

means for activating and deactivating a means to rotate the food container about a vertical axis over the heating means;

means for selectively activating and deactivating each of the plurality of food dispensing means in accordance with food quantities set forth in a selected recipe which has been stored in the first memory means;

means for activating and deactivating the stirring manipulator to stir the solid and liquid foods in the food container means.

6. An apparatus according to claim 1, wherein the dispensing means for dispensing solid foods includes:

a rotatable food tray, having a plurality of solid food sections divided into separate section compartments in the tray;

means to rotate the tray so that the solid foods in each section compartment may be successively added to the food container means through a sector-shaped opening in the base of the tray.

7. An apparatus according to claim 1, wherein the dispensing means for liquid foods includes:

liquid container means, each liquid container holding a single liquid ingredient;

tube means connecting each of the liquid container means to a valve means;

funnel means for receiving the liquid ingredients from each of the valves and directing the liquid ingredients into the food container means.

8. An apparatus according to claim 1, further comprising a temperature measuring means including:

a temperature sensor positioned inside a thermocouple protection tube and biased against the exterior of the base of the food container means for sensing the temperature of the food container means;

conversion means for receiving electrical signals from the temperature sensor and outputting digital temperature signals corresponding to the temperature of the food container means to the digital processing means.

9. An apparatus according to claim 1, wherein the stirring manipulator means includes:

a spatula with a blade and a handle;  
a spatula arm connected pivotally to the handle of the spatula;

a vertical reciprocating linear motion means attached to the spatula arm;

a first driving means coupling the vertical reciprocating linear motion means to a first motor means to drive the spatula arm in a vertical reciprocating linear motion, thereby sweeping the spatula blade down the inside surface of the food container on a downward motion of the spatula arm and drawing the blade of the spatula back on an upward motion of the spatula arm;

a cam operably attached perpendicularly to the end of a cam rod, the cam projecting horizontally to a

**23**

position directly beneath the handle of the spatula,  
the cam rod operably mounted rotatably to a cam  
rod support means;  
a second driving means operably coupling the cam  
rod to the first motor means thereby transmitting a  
counterclockwise rotary motion of the first motor

**24**

means to a clockwise rotary motion of the cam, the  
cam rotating to contact and lift the spatula handle  
thereby lifting the blade of the spatula from the  
inside surface of the food container as the blade of  
the spatula is drawn back.
